GREAT BARRIER REEF
FEATURES ABOVE MEAN HIGH WATER
AT NOVEMBER 1974

CANBERRA, AUSTRALIA.

1975

Division of National Mapping

GREAT BARRIER REEF -
FEATURES ABOVE MEAN HIGH WATER AT NOVEMBER 1974

1. Survey

An aerial inspection was carried out in November 1974 of the Great Barrier Reef from latitude 24°S, south of The Bunker Group, to latitude 10°S, at about the centre of Torres Strait, and extending about 5 miles seaward of the edge of the Reef.

All features above mean high water (MHW) were noted and separated into two categories, those considered to be impermanent, being likely to move or disappear with the changing of the seasons or in storms, and those considered to be permanent and stationary. The features include sand cays, man-made structures, coral boulders and continental islands where they are close to the reef.

The map at attachment A shows all the features above MHW.

2. Straight Baselines

Neither the Reef proper nor Swain Reefs can be enclosed by straight baselines drawn between islands. There are no MHW elevations on the outer Reef between Swain Reefs and Cairns, a distance of 450 nautical miles. Apart from washed-up boulders there are only five permanent cays along the outer edge of the Reef.

There are only two navigation markers on the outer edge of the Reef, one on Raine Island at latitude 11°35' and the other on Euston Reef, off Cairns *.

3. Continuity of the Outer Reef

Except for the section from Cairns to Townsville the outer edge of the Reef may be termed continuous, in the sense that there is no gap between adjacent reefs greater than five miles. A number of isolated reefs lie outside the main reef.

4. Permanency

The likely permanency of each feature was assessed on the following basis:-

Impermanent - bare sand, navigation beacons and other steel or wooden structures.

.../2

* See chart 'Marine Navigational Aids' published by Coastal Services Division, Surface Transport Group, Department of Transport.

Permanent - sand with grass, scrub or trees or with mangroves adjacent, coral boulders washed well up onto a reef, non-coralline or continental islands.

Many sand cays had been proved to move, either continuously, as observed by ground parties at Hixson Cay, or by being washed away and reforming with the change of seasons, as noted on previous successive inspections *.

The inclusion of washed-up boulders may be questioned but, other things being equal, a more violent storm will be necessary to wash them off than that which put them there, and if such an extraordinarily high sea were to arise it could equally well wash away some of the more exposed vegetated cays. Field parties have used large boulders as survey stations from time to time and have reported new coral growth around their bases cementing the boulders into place.

The criterion of grass growth as an indication of permanency was based on the presence of hundreds of birds on most cays of reasonable height. If a cay were to endure a year or more it would certainly have received and germinated much bird-carried seed. Some unvegetated cays were in fact very substantial in both area and height but were classed as impermanent.

A further inspection and photography of the larger unvegetated cays during the north-east season, December to March, would give some indication of how much they change shape and move. A new concept, of permanency allied with constant changing of shape and movement over a small area, might be developed.

5. Records

At Attachment B is an index showing each 1:250 000 map area over the Reef. In some map areas there were no features above MHW and in others there were only continental islands close inshore; these areas have been annotated accordingly.

For each of the remaining map areas lists are attached at C of the permanent and impermanent features with geographical coordinates and references to photographs held in Bathymetric Branch, Division of National Mapping, Canberra.

A set of 1:250 000 maps is held in Technical Services Section Canberra showing the features above MHW,

.../3

* See previous National Mapping reports 74/616/47 and 74/616/71 of May 1971.

Original observations are recorded in Spot Photography Field Books 14518 and 14519, held in Technical Services Canberra.

All the negative observations, that is, the absence of previously sighted cays, and other notes are recorded only on the set of field maps held in Bathymetric Branch, Canberra.

6. Photographs

All features above MHW were photographed on 35 mm colour negative film, using an ultra violet filter and a zoom lens, generally but not always set at focal length 86 mm, and on 70 mm black and white film using a polarizing filter and a focal length of 50 mm. The latter were mostly taken in pairs one second apart to give a stereoscopic image.

All photographs were hand-held obliques taken through an open window.

Flying heights were between 500 feet and 3000 feet, as dictated by the average size of the features in the area, cloud height, visibility in rain and the radius of vision required for navigation. The height and camera direction for each black and white photograph are annotated on its border; the corresponding colour photograph is found by cross reference on the list of features at Attachment C.

Several flights were made to rephotograph features at mean low water \pm 0.3 metres for a visual comparison of the tide height. These photographs are also listed at Attachment C.

7. Maps

The Great Barrier Reef Reconnaissance Series, a one-colour map at 1:250 000 scale, accurately shows the outline of all reefs between the southern end of the Reef and latitude 14°S at about Princess Charlotte Bay. North of this point, until such time as air photography or satellite photography becomes available, while the general location of the reef is correct small details are not reliable and features noted at sea cannot always be accurately plotted.

However only two features above MHW are of doubtful accuracy in position at this time; they are impermanent sand cays at about 10°08'S 143°58'E and at 11°34'S 143°48'E.

8. Tide Predictions

Inspection Flights were timed to cover the Reef when the predicted tide in the area was within 0.3 metres of MHW.

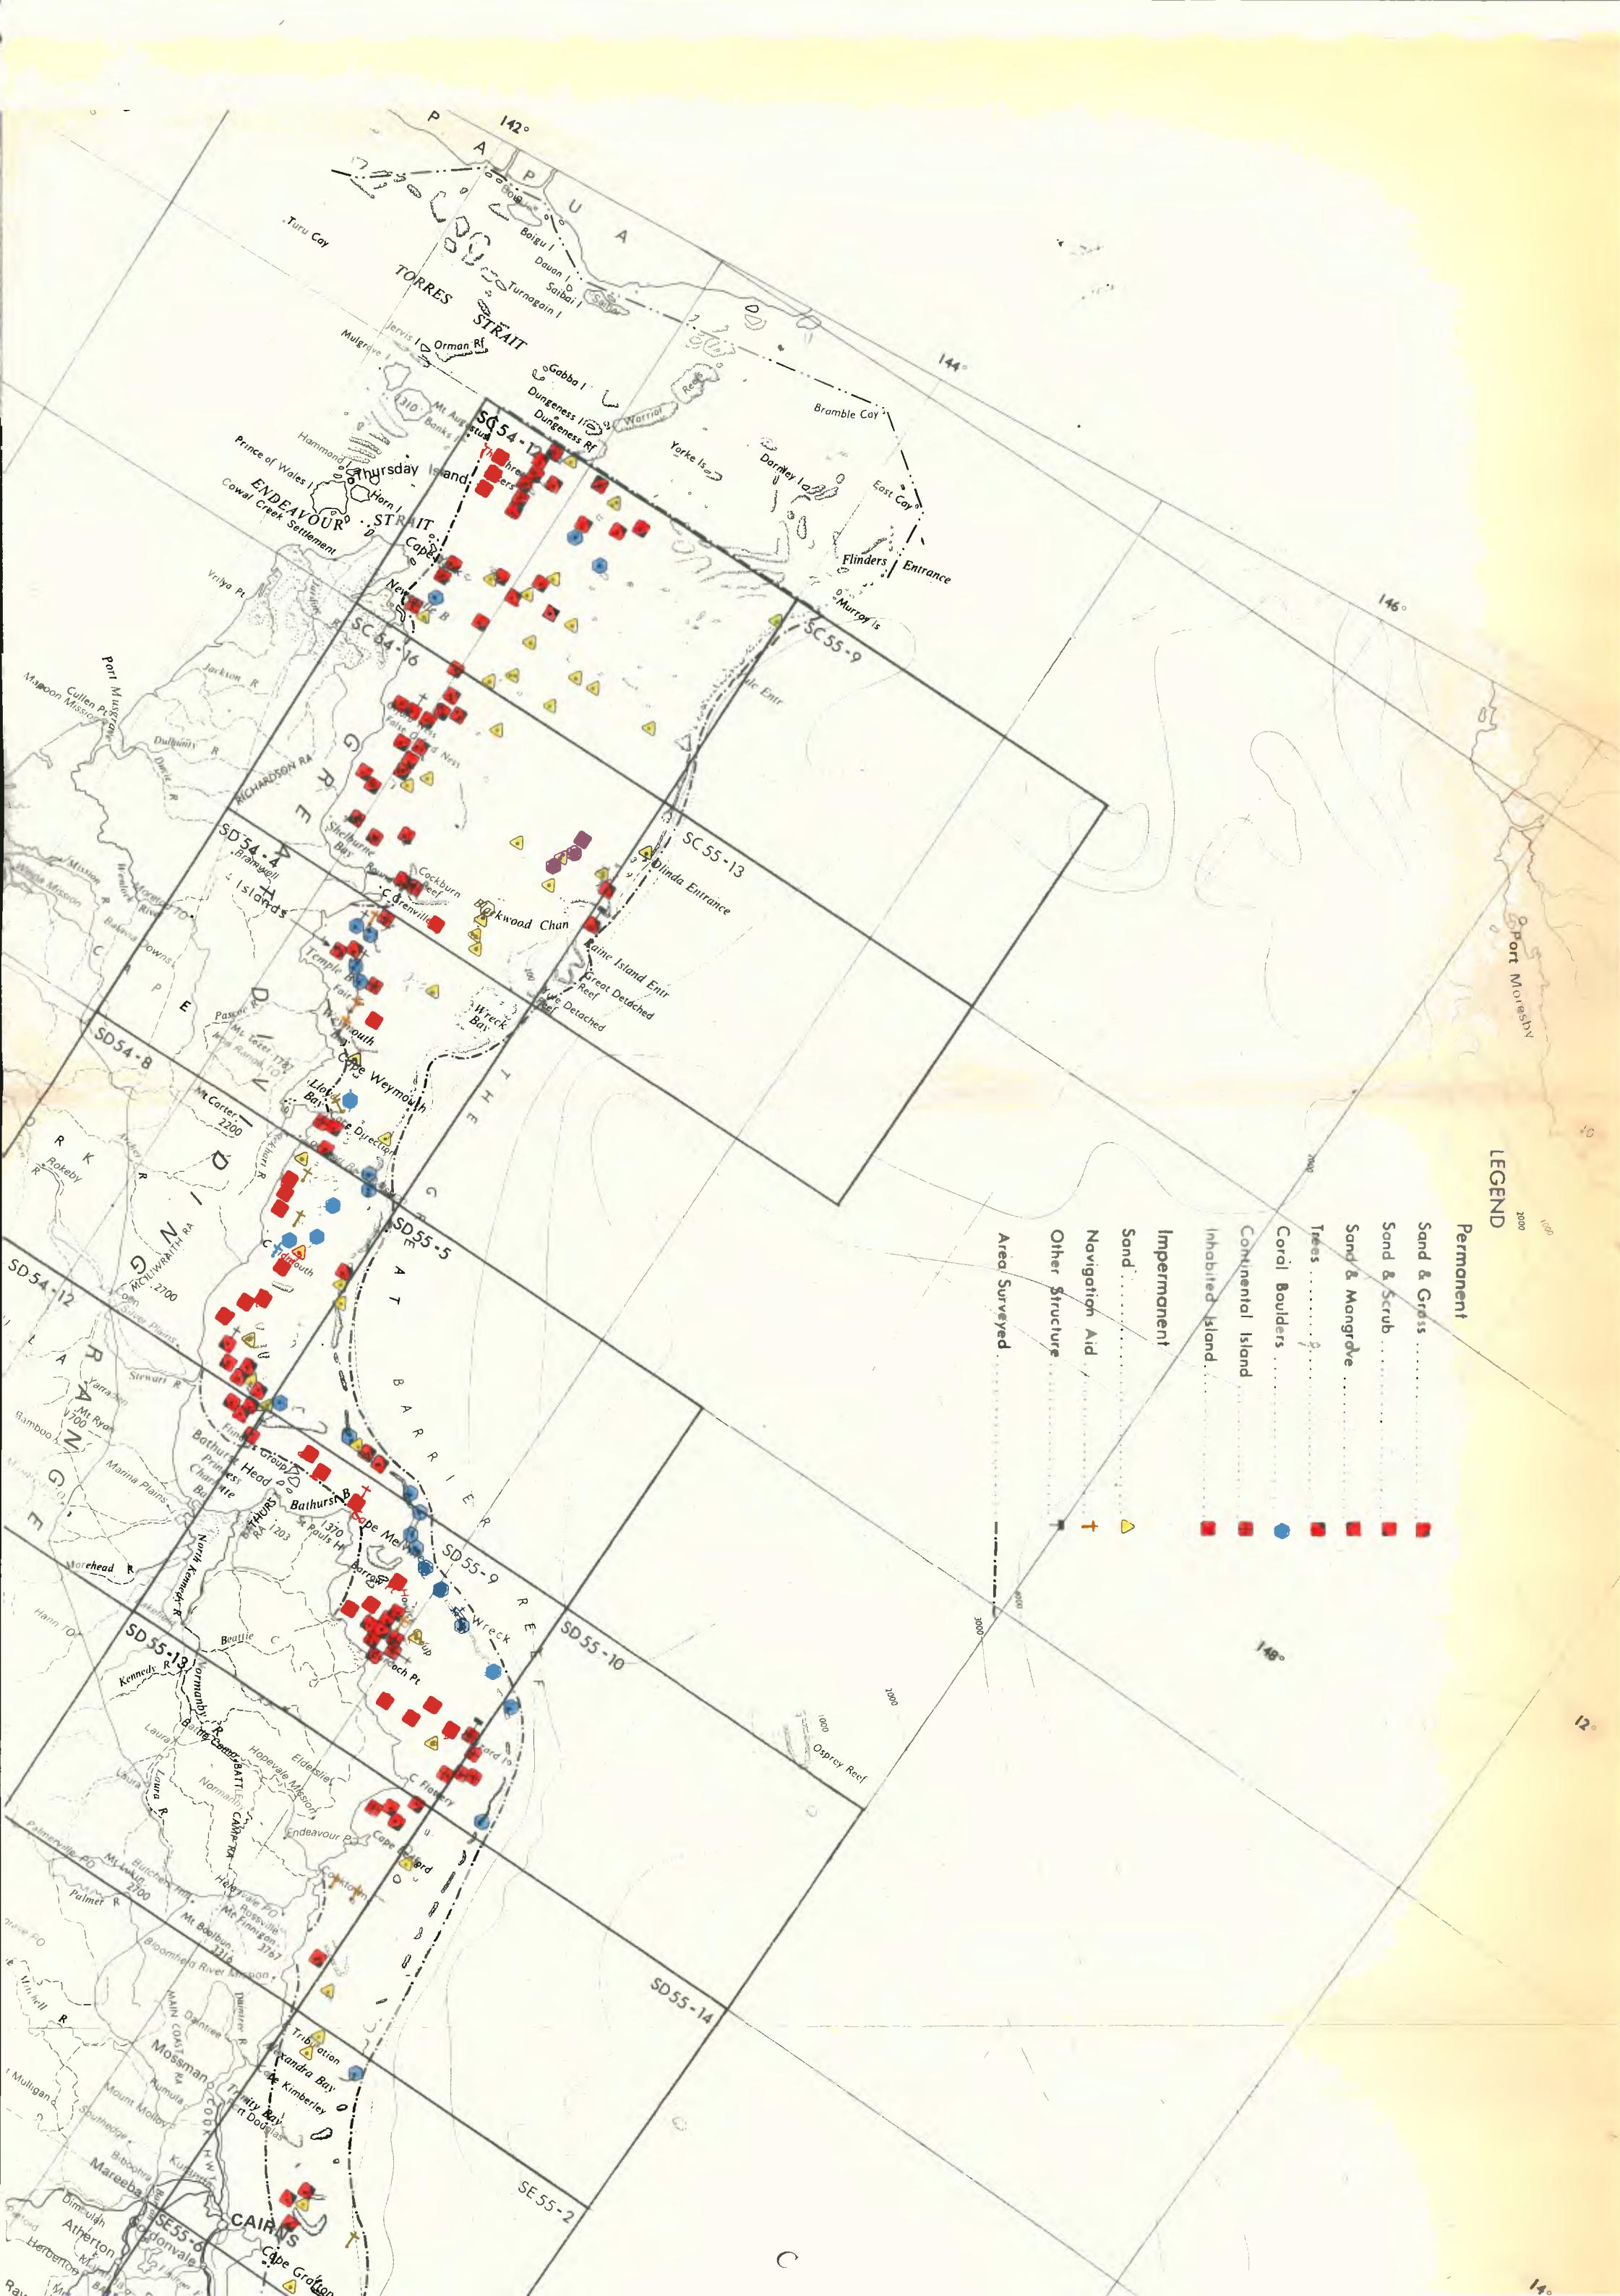

The decrease of tidal range with distance offshore and inaccuracies in transferring predictions from inshore islands to the outer reef made it pointless to use high precision in tidal calculations. A form used for prediction of the times of MHW + 0.3 metres and a sample calculation are at Attachments D and E. The times refer to Secondary Ports as listed in the Australian Tide Tables and were transferred to the outer reef using lines of simultaneous high tide, or cotidal lines +.

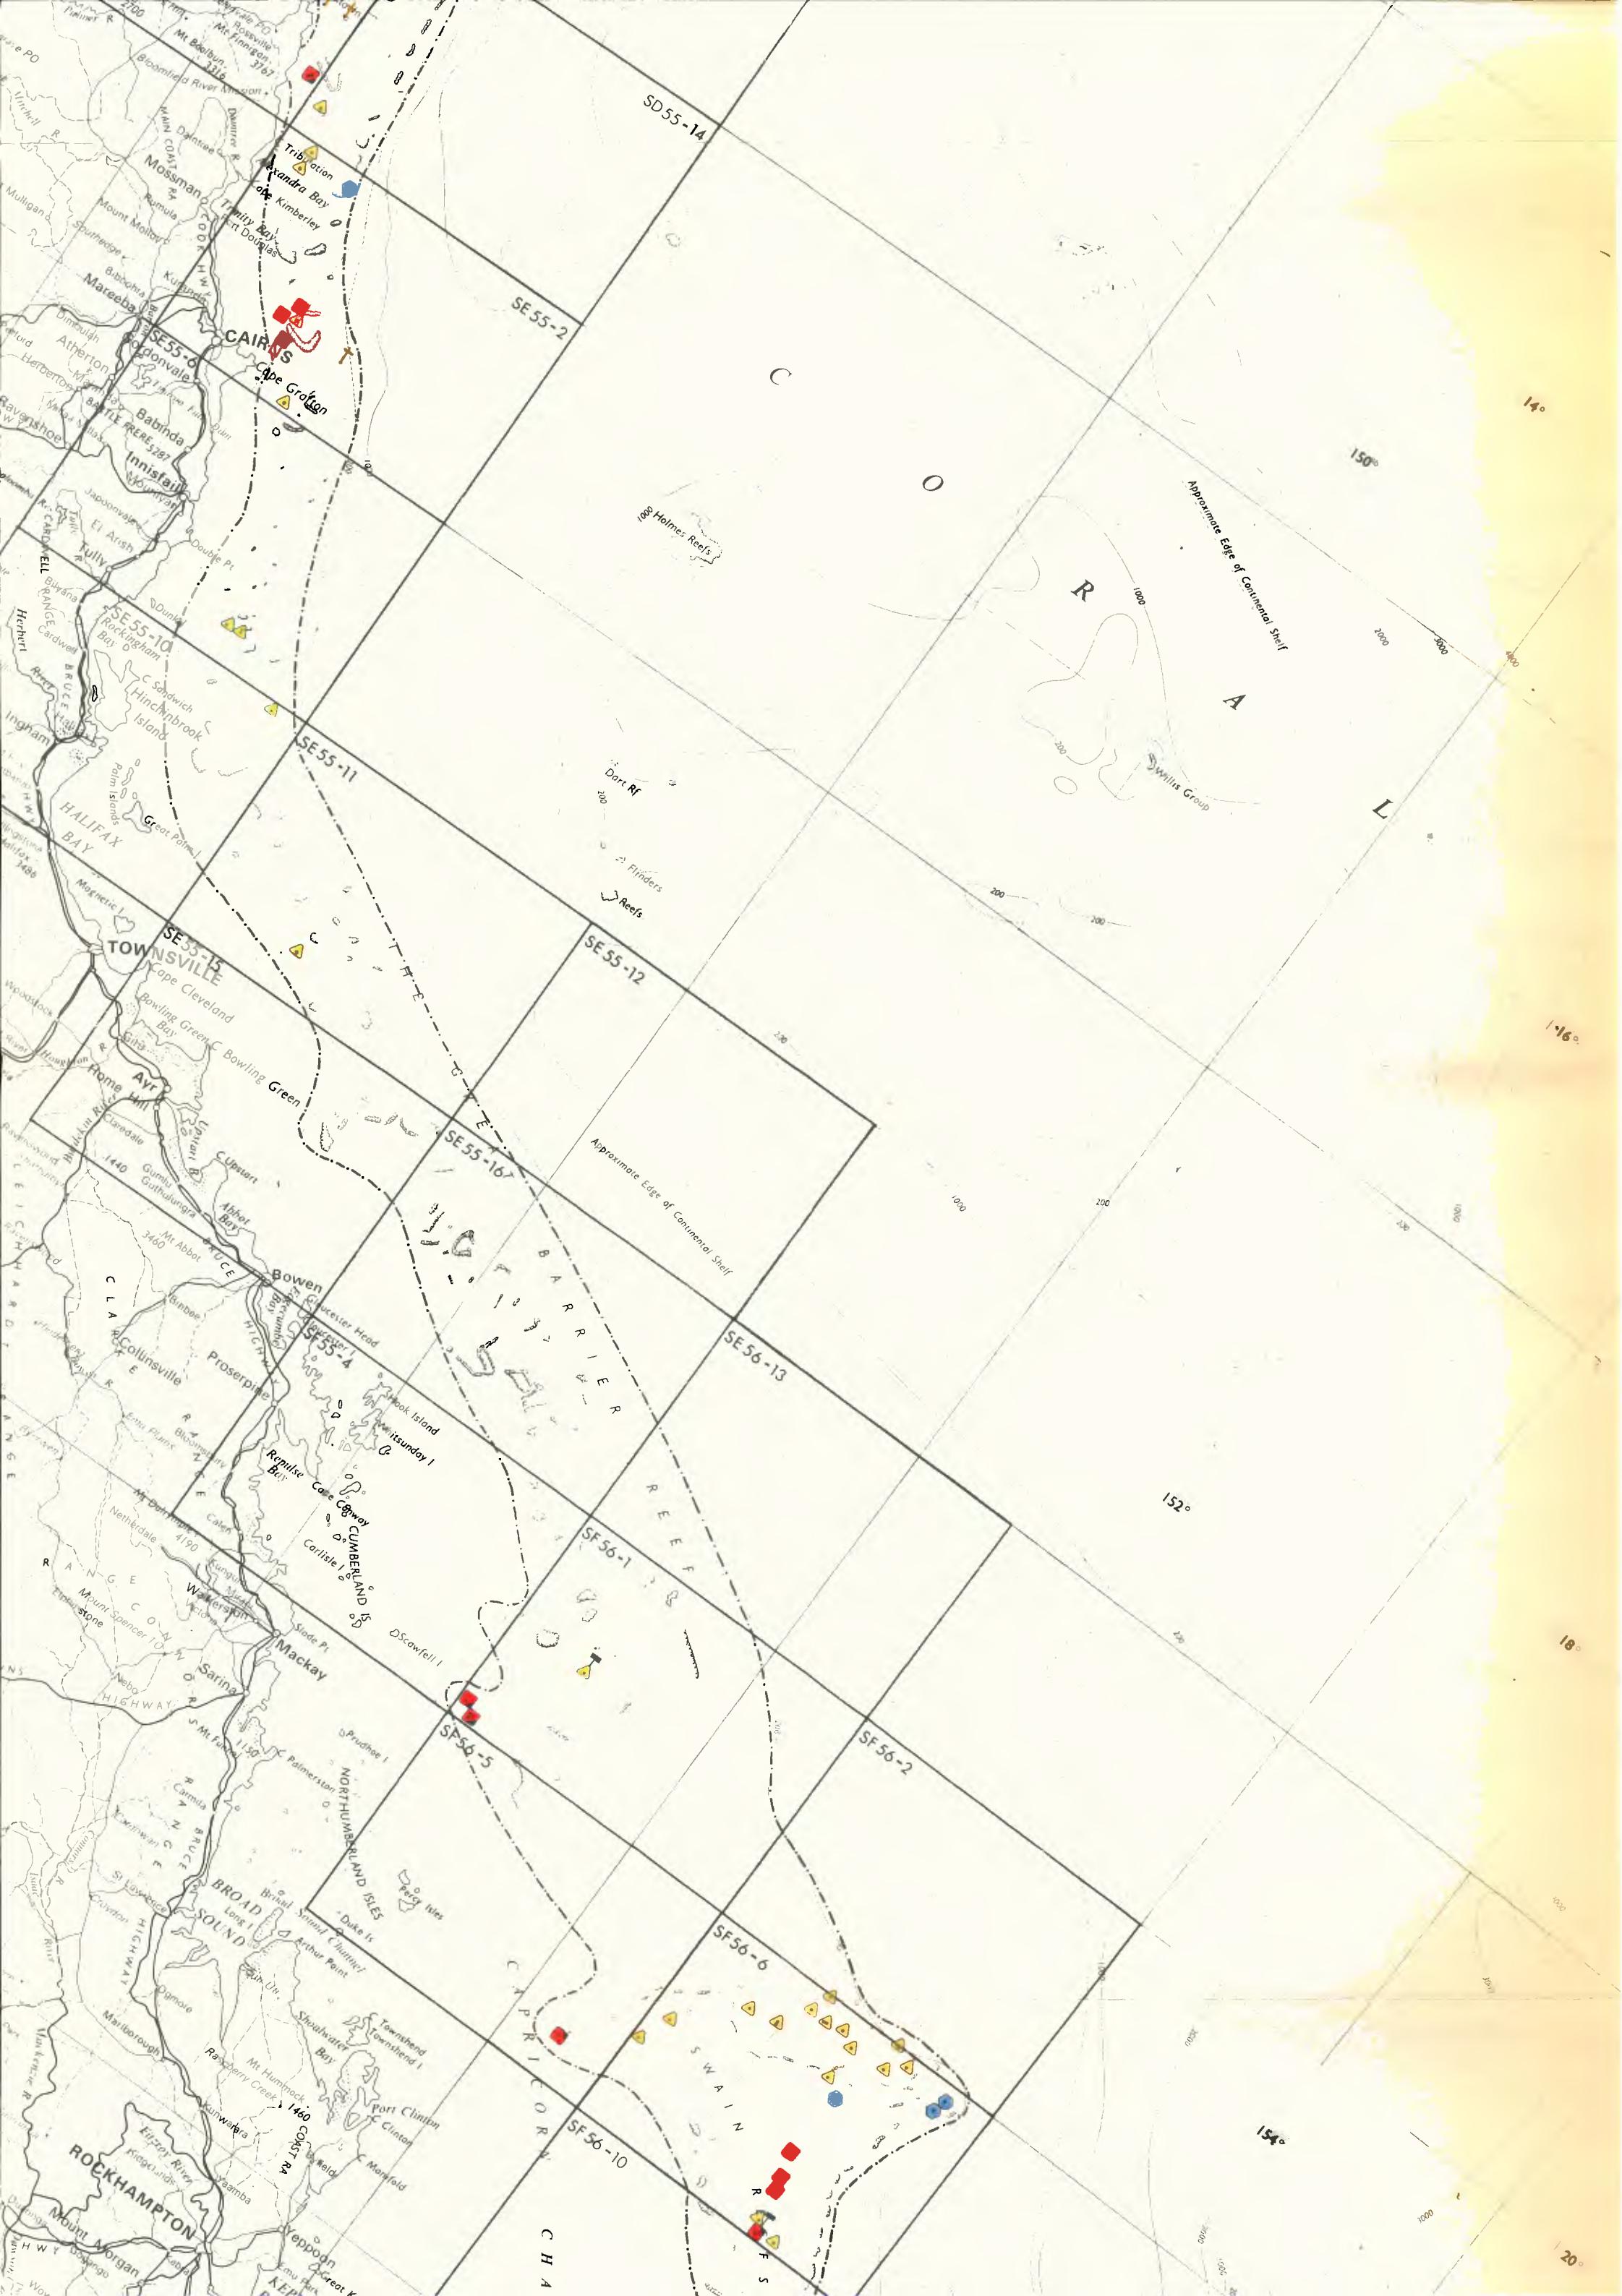

The tolerance of 0.3 m above and below MHW occasionally allowed inspection periods of up to six hours. At other times the predicted high water did not reach 0.3 m below MHW and the only productive flying time available was to clear areas as having no features above MHW.
